Developing Algorithms based on Dynamic Programming

Objects: optimization problems

problem of finding an optimal solution among those satisfying given constraints.

Problem solving by dynamic programming

1. Characterize a structure of an optimal solution.
2. Define an optimal solution **recursively**.
(construct a solution using solutions to subproblems)
3. Compute a value of an optimal solution in a **bottom-up manner** (in the way to fill in a table)
4. Construct an optimal solution using information obtained.
(not only finding a value of an optimal solution but also constructing an optimal solution by following in the table)

Term of “Dynamic Programming”

- **Dynamic programming** has no concrete definition (as far as I know); it is a method/strategy/idea that
 1. Define a problem recursively, and
 2. Solve the problem without (exponential) recursions
- **We show “examples” that dynamic programming technique works**
 1. Combinations (and Fibonacci)
 2. Longest common subsequence
 3. Knapsack problem (NP-complete problem!?)
 4. Chained matrix product

Number of combinations

Problem P1: Compute the number $C(n, k)$ of combinations to choose k items from n different items.

Using the formula,

$$C(n, k) = C(n-1, k-1) + C(n-1, k), \text{ if } 0 < k < n,$$

$$C(n, 0) = C(n, n) = 1.$$

Therefore, we have the following program.

```
int C(int n, int k){
    if(k==0 || k==n) return 1;
    return C(n-1, k-1) + C(n-1, k);
}
```

When you implement the program in practice, you will find that it takes much time. Why does it take time?

Analysis of computation time:

Let $T(n, k)$ be time to compute $C(n, k)$. Then, we have $T(n, k) = T(n-1, k-1) + T(n-1, k)$. Thus, $T(n, k) = O(C(n, k))$. This is an **exponential function**.

Let's analyze behavior of the program!

How is the function called

The function is called many times for the same value.

Example: $C(3,2)$ is called twice. \rightarrow redundant

If we store the value $C(n,k)$ as the (n,k) element of an array when it is first computed, then the same value is never computed twice. Basically, it suffices to fill in the table.

Fill in the table $C(n,k)$!

Formula: $C(n,k) = C(n-1,k-1) + C(n-1,k)$

If the values in the $(n-1)$ -st row are available, $C(n,k)$ is easily computed. \rightarrow Thus, we should fill in the table from the 1st row.

	0	1	2	3	4	5
0	1					
1	1	1				
2	1	2	1			
3						
4						
5						

	0	1	2	3	4	5
0	1					
1	1	1				
2	1	2	1			
3	1	3	3	1		
4						
5						

	0	1	2	3	4	5
0	1					
1	1	1				
2	1	2	1			
3	1	3	3	1		
4	1	4	6	4	1	
5						

	0	1	2	3	4	5
0	1					
1	1	1				
2	1	2	1			
3	1	3	3	1		
4	1	4	6	4	1	
5	1	5	10	10	5	1

Each element of the table can be computed in constant time.

Thus, the total time is $O(n^2)$.

C program is as follows :

```
int C(int n, int k){
    C[0][0]=1;
    for(i=1; i<=n; i++){
        C[i][0]=1; C[[i][i]=1;
        for(j=1; j<i; j++)
            C[i][j] = C[i-1][j-1] + C[i-1][j];
    }
    return C[n][k];
}
```

Exercise E1: Investigate an algorithm that computes $C(n,k)$ based on the Naïve idea in linear time such that it computes $C(n,k)$ correctly if $C(n,k)$ itself does not overflow.

Naive Algorithm 2:

Using the formula $C(n,k) = \frac{n!}{(n-k)! k!}$, it can be computed in $O(n)$.

Here, note that this algorithm may suffer from numerical overflow.

Computation of Fibonacci number

Problem P2: Compute the Fibonacci number $F(n)$ defined by

$$F(n) = F(n-1) + F(n-2), \quad \text{if } n > 1,$$

$$F(0) = F(1) = 1.$$

Fibonacci number:

1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, ...

Exercise E2: Have an argument similar to that in Problem 1.

Supplemental information:

Using the golden ration $\phi = (1 + \sqrt{5})/2 \doteq 1.61803$,
the Fibonacci number $F(n)$ can be represented as

$$F(n) = O(\phi^n).$$

Longest Common Subsequence

Problem P3: Given two strings A and B of lengths n and m, find the longest substring common to both of them.

Example: For A = G A A T T C A G T T A and B = G G A T C G A, the longest common substring is GATCA.

A = GAATTC AGTTA

B = GGA T CGA

Any substring A' of A is a substring of B if characters of A' appear in the same order in the string B.

→ It can be determined in linear time.

Exercise E3: Write a program to determine whether the first string of two input strings is a substring of the second string in linear time.

Algorithm P3-A0: (Brute-Force Algorithm)

For each substring A' of a string A , determine whether A' is a substring of a string B , and finally output the longest common substring.

Analysis of computation time:

- There are 2^n different substrings of a string of length n .
- If this substring is longer than the string B , obviously it is not a substring of B .
- Otherwise, each test takes $O(m)$ time.
- Thus, the total time is $O(2^n m)$ time.

Is it possible to have faster algorithm?

Is there any polynomial-time algorithm?

Algorithm P3-A1:

$A = a_1 a_2 \dots a_n$, $B = b_1 b_2 \dots b_m$

$L[i,j]$ = the length of the longest substring common to $a_1 a_2 \dots a_i$ and $b_1 b_2 \dots b_j$

Observation:

(0) if $i=0$ or $j=0$, $L[i,j]=0$.

(1) $a_i = b_j \rightarrow L[i,j] = L[i-1,j-1] + 1$

(2) $a_i \neq b_j \rightarrow L[i,j] = \max \{ L[i,j-1], L[i-1, j] \}$

Key point of DP is finding such a definition of table!

A=GAATTC AGTTA
B= GGATC GA
when $a_i = b_j$

A=GAATTC AGTTA
B=GGATCG A
when $a_i \neq b_j$

Therefore, it suffices to fill in the table $L[i,j]$ in order. Since the table size is $n \times m$, it takes $O(nm)$ time.

Algorithm P3-A1:

```
for(i=0; i<=n; i++)
  L[i][0]=0;
for(j=0; j<=m; j++)
  L[0][j] = 0;
for(i=1; i<=n; i++)
  for(j=1; j<=m; j++)
    if( a[i] == b[j]) L[i][j] = L[i-1][j-1]+1;
    else L[i][j] = max{ L[i][j-1], L[i-1][j] };
return L[n][m];
```

Example for the case

A=XYXXZXYZXY and

B=ZXZYZZXXYXXZ

A= X Y XXZXYZXY,

B=ZXZYZZXXYXXZ

	0	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	0	0	0	0	0	0	0	0	0	0	0
1	0	0	1	1	1	1	1	1	1	1	1	1	1
2	0	0	1	1	2	2	2	2	2	2	2	2	2
3	0	0	1	1	2	2	2	3	3	3	3	3	3
4	0	0	1	1	2	2	2	3	4	4	4	4	4
5	0	1	1	2	2	2	3	3	4	4	4	4	5
6	0	1	2	2	2	2	3	4	4	4	5	5	5
7	0	1	2	2	3	3	3	4	4	5	5	5	5
8	0	1	2	3	3	3	4	4	4	5	5	5	6
9	0	1	2	3	3	3	4	4	5	5	6	6	6
10	0	1	2	3	4	4	4	5	5	6	6	6	6

Construction of an optimal solution

The value of an optimal solution is obtained by filling in the table. How can we construct an optimal solution achieving the value?

In the problem of finding the longest common substring, we want to find not only the length (**value of an optimal solution**) but also the longest such substring (optimal solution) itself.

When we fill in the table, we memorize which table element determined $L[i][j]$.

- (1) $a_i = b_j \rightarrow L[i,j] = L[i-1,j-1] + 1$
(i-1, j-1) is memorized
- (2) $a_i \neq b_j \rightarrow L[i,j] = \max \{ L[i,j-1], L[i-1, j] \}$
if $L[i,j-1] > L[i-1, j]$ then (i, j-1) is memorized, and otherwise, (i-1, j) is memorized.

Concrete program

```
for(i=1; i<n; i++)
  for(j=1; j<m; j++){
    if( A[i] == B[j] ){
      L[i][j] = L[i-1][j-1] + 1;
      B1[i][j] = i-1; B2[i][j] = j-1;
    } else {
      L[i][j] = max2(L[i][j-1], L[i-1][j]);
      if( L[i][j-1] > L[i-1][j] ){
        L[i][j] = L[i][j-1];
        B1[i][j] = B1[i][j-1]; B2[i][j] = B2[i][j-1];
      } else {
        L[i][j] = L[i-1][j];
        B1[i][j] = B1[i-1][j]; B2[i][j] = B2[i-1][j];
      }
    }
  }
}
```

Exercise E4: Write a program in practice to see its behavior.

For the case: $A=XYXXZXYZXY$, $B=ZXZYYZXXYXXZ$

Table for backtrack

	1	2	3	4	5	6	7	8	9	10	11	12
1	(0,0)	(0,1)	(0,1)	(0,1)	(0,1)	(0,1)	(0,6)	(0,7)	(0,7)	(0,9)	(0,10)	(0,10)
2	(0,0)	(0,1)	(0,1)	(1,3)	(1,4)	(1,4)	(1,4)	(1,4)	(1,8)	(1,8)	(1,8)	(1,8)
3	(0,0)	(2,1)	(0,1)	(1,3)	(1,4)	(1,4)	(2,6)	(2,7)	(2,7)	(2,9)	(2,10)	(2,10)
4	(0,0)	(3,1)	(0,1)	(1,3)	(1,4)	(1,4)	(3,6)	(3,7)	(3,7)	(3,9)	(3,10)	(3,10)
5	(4,0)	(3,1)	(4,2)	(1,3)	(1,4)	(4,5)	(3,6)	(3,7)	(3,7)	(3,9)	(3,10)	(4,11)
6	(4,0)	(5,1)	(4,2)	(1,3)	(1,4)	(4,5)	(5,6)	(5,7)	(3,7)	(5,9)	(5,10)	(4,11)
7	(4,0)	(5,1)	(4,2)	(6,3)	(6,4)	(4,5)	(5,6)	(5,7)	(6,8)	(5,9)	(5,10)	(4,11)
8	(7,0)	(5,1)	(7,2)	(6,3)	(6,4)	(7,5)	(5,6)	(5,7)	(6,8)	(5,9)	(5,10)	(7,11)
9	(7,0)	(8,1)	(7,2)	(6,3)	(6,4)	(7,5)	(8,6)	(8,7)	(6,8)	(8,9)	(8,10)	(7,11)
10	(7,0)	(8,1)	(7,2)	(9,3)	(9,4)	(7,5)	(8,6)	(8,7)	(9,8)	(8,9)	(8,10)	(7,11)

If we trace the table from $L[10][12]$ in reverse order,

$L[10][12] \rightarrow L[7][11] \rightarrow L[5][10] \rightarrow L[3][9] \rightarrow L[2][7] \rightarrow L[1][4] \rightarrow L[0][1]$
 $a[8]b[12] \quad a[6]b[11] \quad a[4]b[10] \quad a[3]b[8] \quad a[2]b[5] \quad a[1]b[2]$

Thus, the longest common substring is

123456789A **123456789ABC**
XYXXZXYZXY **ZXZYYZXXYXXZ** **XYXXXZ**

Problem P4: (Knapsack Problem)

Given n objects o_i ($i=1, \dots, n$) and their weights w_i , prices v_i , and the capacity (or weight limit) C of a knapsack, find an optimal way of packing objects into the knapsack to meet the capacity constraint in such a way that the total price is maximized.

Input: $I = \{w_1, \dots, w_n; v_1, \dots, v_n; C\}$. A solution is represented by a subset S of $\{1, 2, \dots, n\}$.

An optimal solution is such a set S satisfying the

$$\text{Capacity constraint} \quad \sum_{i \in S} w_i \leq C$$

and maximizing

$$\text{total sum of prices} \quad \sum_{i \in S} v_i.$$

Assumption: Assume that weight of any object does not exceed the capacity C because any object with weight exceeding C is never selected.

Example: Consider the case in which $(w_1, \dots, w_5) = (2, 3, 4, 5, 6)$,
 $(v_1, \dots, v_5) = (4, 5, 8, 9, 11)$, $C = 10$.

$V[k]$ = value of an optimal solution for objects up to the k -th one.

Then, by the definition

$$V[1] \leq V[2] \leq \dots \leq V[n].$$

In this example, we have

$$V[1] = v_1 = 4, w_1 = 2 \leq C,$$

$$V[2] = v_1 + v_2 = 4 + 5 = 9, w_1 + w_2 = 2 + 3 \leq C,$$

$$V[3] = v_1 + v_2 + v_3 = 4 + 5 + 8 = 17, w_1 + w_2 + w_3 = 2 + 3 + 4 \leq C,$$

$$V[4] = v_1 + v_2 + v_4 = 4 + 5 + 9 = 18, w_1 + w_2 + w_4 = 2 + 3 + 5 \leq C,$$

$$V[5] = v_3 + v_5 = 8 + 11 = 19, w_3 + w_5 = 4 + 6 \leq C.$$

Here, $\{1, 2, 3, 4\}$ is not a solution since the total weight exceeds the capacity 10.

In this example, an optimal solution to a subproblem may not be included in an optimal solution. Thus, we cannot apply Dynamic Programming to find a solution in the above order.

Then, what about a method to examine all possible ways of choosing objects?

For each object there are two ways, to choose or not to choose.
⇒ there are 2^n ways to choose objects.
It takes exponential time if we examine all possible cases.

To apply Dynamic Programming, an optimal solution must be defined recursively so that it includes a solution to a subproblem.

$D[i,j]$ = the largest total price among all possible ways to choose objects from objects 1, ..., i so that the total weight is j.
It is 0 if there is no way to choose them so that the total weight is j.

If an optimal solutions for objects 1,...,i-1 is known, we just consider two cases, to add an object i and not to add it. Thus, we have

$$D[i,j] = \max\{D[i-1, j], D[i-1, j-w_i]+v_i\}$$

This implies the property of **Optimal Substructure**.

Example: Let $(w_1, \dots, w_5) = (2, 3, 4, 5, 6)$, $(v_1, \dots, v_5) = (4, 5, 8, 9, 11)$, $C = 10$.

$i=1 \rightarrow$ only two ways to choose object 1 or not choose it:

$$D[1, w_1] = D[1, 2] = v_1 = 4, \quad D[1, j] = 0, \quad j \neq 2,$$

$i=2 \rightarrow$ there are four cases: $\{\}, \{1\}, \{2\}, \{1, 2\}$

$$D[2, 2] = 4, \quad D[2, 3] = 5, \quad D[2, 5] = 9, \quad D[2, j] = 0 \quad j \neq 2, 3, 5$$

k	2	3	4	5	6	7	8	9	10
0	0	0	0	0	0	0	0	0	0
1	4								
2	4	5		9					
3	4	5	8	9	12	13		17	
4	4	5	8	9	12	13	14	17	18
5	4	5	8	9	12	13	15	17	19

 indicates a new solution

$$w_1 = 2, v_1 = 4$$

$$w_2 = 3, v_2 = 5$$

$$w_3 = 4, v_3 = 8$$

$$w_4 = 5, v_4 = 9$$

$$w_5 = 6, v_5 = 11$$

We can ignore a set of objects if their total weight exceeds 10. 19/40

Algorithm P4-A0:

Input: n objects $o_i (i=1, \dots, n)$: weight w_i and price v_i , capacity C .

```
for(i=1; i<=C; i++)
    D[0,i] = 0;
for(k=1; k<=n; k++)
    for(i=1; i<=C; i++)
        if(i < wi) D[k,i] = D[k-1,i];
        else {
            if(D[k-1,i-wi]+vi > D[k-1,i])
                D[k,i] = D[k-1,i-wi]+vi;
            else
                D[k,i] = D[k-1, i];
        }
max=0;
for(i=1; i<=C; i++)
    if(D[n,i]>max) max = D[n,i];
return max;
```

We want to construct an optimal solution with the value of optimal solution.

We maintain not only the table $D[i,j]$ but also the combination to give the value of $D[i,j]$.

$$D[i,j] = \max\{D[i, j-1], D[i-w_j, j-1] + v_j\}$$

$$T[i,j] = j \quad \text{if } D[i,j] = D[i-w_j, j-1] + v_j$$

$$T[i,j] = 0 \quad \text{if } D[i,j] = D[i, j-1]$$

Then, we can construct an optimal solution by tracing back the value of D from $D[i,n]$ giving the optimal solution.

k	2	3	4	5	6	7	8	9	10
0	0	0	0	0	0	0	0	0	0
1	4/1								
2	4/0	5/2		9/2					
3	4/0	5/0	8/3	9/0	12/3	13/3		17/3

5	4/0	5/0	8/0	9/0	12/0	13/0	15/5	17/0	19/5

values of $D[i,j]/T[i,j]$

k	2	3	4	5	6	7	8	9	10
0	0	0	0	0	0	0	0	0	0
1	4/1								
2	4/0	5/2		9/2					
3	4/0	5/0	8/3	9/0	12/3	13/3		17/3	
4	4/0	5/0	8/0	9/0	12/0	13/0	14/4	17/0	18/4
5	4/0	5/0	8/0	9/0	12/0	13/0	15/5	17/0	19/5

Values of $D[i,j]/T[i,j]$

The value of an optimal solution is given by $D[5,10]=19$.

$D[5,10]=19$, $T[5,10]=5 \neq 0$, output object 5.

Since $w_5=6$, its predecessor is $D[4,10-6]=D[4,4]$,

$D[4,4]=8$, $T[4,4]=0$, output nothing. The predecessor is $D[3,4]=8$.

$D[3,4]=8$, $T[3,4]=3 \neq 0$, output object 3.

Since $w_3=4$, its predecessor is $D[2,4-4]=D[2,0]$.

Now the total weight becomes 0, and thus this is the end.

After all, the set of objects for an optimal solution is $\{3,5\}$.

Algorithm P4-A1:

Input: n objects o_i ($i=1, \dots, n$): weight w_i and price v_i , capacity C .

```
for(i=0; i<=C; i++)
    D[0,i] = T[0,i]=0;
for(k=1; k<=n; k++)
    for(i=1; i<=C; i++)
        if(i < wk) { D[k,i] = D[k-1,i]; T[k,i]=0;}
        else {
            if(D[k-1,i-wk]+vk > D[k-1,i])
                {D[k,i] = D[k-1,i-wk]+vk; T[k,i]=k;}
            else
                {D[k,i] = D[k-1, i]; T[k,i]=0;}
        }
k=0;
for(i=1; i<=C; i++)
    if(D[n,i]>D[n, k]) k = i;
for(i=n; i>0 && k>0; i--)
    if( T[i,k] > 0) {
        Output T[i,k]; k = k - wi;
    }
```

Analysis of Computation Time

From the structure of the algorithm the computation time is given by $O(nC)$.

(1) If the capacity C is polynomial in the number n of objects
 \Rightarrow this computation time is a polynomial in n .

(2) If C is much larger than n .

The value C itself can be represented by $\log C$ bits.

\Rightarrow Time is proportional to an exponential function in input size.

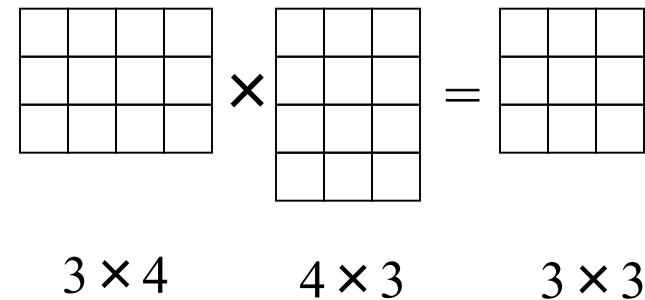

It is called **a pseudo-polynomial time algorithm**.

Exercise E5: Algorithm P4-A1 uses two 2-dimensional arrays. Show that one of them can be replaced by a one-dimensional array.

Problem P5: (Chained Matrix Product)

Given a sequence of n matrices $\langle A_1, A_2, \dots, A_n \rangle$, find an order of matrix products to minimize the number of operations to compute the matrix product $A_1 \times A_2 \times \dots \times A_n$.

Product of a $p \times q$ matrix and $q \times r$ matrix is a $p \times r$ matrix using $p \times q \times r$ operations (multiplication and addition).

The diagram illustrates the multiplication of two matrices. On the left is a 3x4 grid representing a matrix. This is followed by a multiplication symbol (×) and a 4x3 grid representing another matrix. To the right of the multiplication symbol is an equals sign (=) and a 3x3 grid representing the resulting matrix. Below each grid is its respective dimension: 3 × 4, 4 × 3, and 3 × 3.

Example: $A_1=10 \times 20$ matrix, $A_2=20 \times 5$ matrix, $A_3=5 \times 25$ matrix.
 $((A_1 \times A_2) \times A_3)$ require $(10 \times 20 \times 5) + (10 \times 5 \times 25) = 2250$ ops.
 $(A_1 \times (A_2 \times A_3))$ requires $(10 \times 20 \times 25) + (20 \times 5 \times 25) = 7500$ ops.
Thus, the former needs less operations.

For product of four matrices, there are many orders for their product.

$$((A_1 \times (A_2 \times A_3)) \times A_4)$$

$$(((A_1 \times A_2) \times A_3) \times A_4)$$

$$((A_1 \times A_2) \times (A_3 \times A_4))$$

$$(A_1 \times ((A_2 \times A_3) \times A_4))$$

$$(A_1 \times (A_2 \times (A_3 \times A_4)))$$

Precisely,
$$\frac{1}{n+1} \binom{2n}{n}$$

It suffices to obtain the number of operations for all of them.

Exercise E6: Prove that there are $O(4^n/n^{3/2})$ ways for parenthesizations. This is known as the Catalan number.

Hint: Suppose there are $P(n)$ ways for parenthesization. In each sequence we can parenthesize it by dividing it between its k -th and $(k+1)$ -st position into subsequences independently. Thus, we have

$$P(1) = 1$$

$$P(n) = \sum_{k=1}^{n-1} P(k)P(n-k)$$

Due to Richard P. Stanley, the Catalan number has 207 representations!
(See <http://www-math.mit.edu/~rstan/ec/>)

Characterize structure of an optimal solution and define the value of an optimal solution recursively.

To compute the product of 4 matrixes

$((A_1 \times (A_2 \times A_3)) \times A_4)$ last is the product of (A_1, A_2, A_3) and A_4

$((A_1 \times A_2) \times A_3) \times A_4$ last is the product of (A_1, A_2, A_3) and A_4

$((A_1 \times A_2) \times (A_3 \times A_4))$ last is the product of (A_1, A_2) and (A_3, A_4)

$(A_1 \times ((A_2 \times A_3) \times A_4))$ last is the product of A_1 and (A_2, A_3, A_4)

$(A_1 \times (A_2 \times (A_3 \times A_4)))$ last is the product of A_1 and (A_2, A_3, A_4)

If we know an optimal orders for subsequences, it suffices to check the three ways of partitions.

$((A_1, A_2, A_3), A_4), ((A_1, A_2), (A_3, A_4)), (A_1, (A_2, A_3, A_4))$

Generally, the problem is the place for the first partition.

$((A_1, \dots, A_k), (A_{k+1}, \dots, A_n))$ $k=1, 2, \dots, n-1$

If we know an optimal order for computation for each subsequence, then an optimal order for computation is obtained.

Let the size of each matrix be $p_i \times q_i$. Then, only if we have

$$q_1 = p_2, q_2 = p_3, \dots, q_n = p_{n+1}$$

the product of those matrices is defined.

Thus, we only specify $p_1, p_2, \dots, p_n, p_{n+1}$ for input.

If we take the product of matrices from A_i to A_j
then the $p_i \times q_j = p_{j+1}$ matrix is obtained.

We define as follows:

$M[i,j]$ = the smallest number of computations to calculate
the product of matrices from A_i to A_j .

We define as follows:

$M[i,j]$ = the smallest number of computations to calculate the product of matrices from A_i to A_j .

For the computation it suffices to evaluate all possible productions of matrices from A_i to A_k and those from A_{k+1} to A_j for each k between i and j .

The product for A_i through A_k is a $p_i \times p_{k+1}$ matrix, and that for A_{k+1} through A_j is a $p_{k+1} \times p_{j+1}$ matrix.

Thus, the number of operations to compute them is $p_i p_{k+1} p_{j+1}$.

Therefore, the recurrence equation for $M[i,j]$ is

$$M[i, j] = \min \{M[i,k]+M[k+1,j]+p_i p_{k+1} p_{j+1}, k=i, i+1, \dots, j-1\}.$$

algorithm P5-A0:

input: matrix sizes $(p_1 \text{ rows } p_2 \text{ columns}), (p_2, p_3), \dots, (p_n, p_{n+1})$.

```
for(i=1; i<=n; i++)
```

```
    M[i,i] = 0;
```

```
for(d=1; d<=n; d++)
```

```
    for(i=1; i<=n-d; i++)
```

```
        j=i+d;
```

```
        msf = M[i,i]+M[i+1,j]+pipi+1pj+1;
```

```
        for(k=i; k<j; k++)
```

```
            if( M[i,k]+M[k+1,j]+pipk+1pj+1 < msf)
```

```
                msf = M[i,k]+M[k+1,j]+pipk+1pj+1;
```

```
        M[i,j] = msf;
```

```
    }
```

```
return M[1,n];
```

Exercise E7: The above algorithm only finds the value of an optimal solution. Modify it so that an optimal order of computation is also obtained.

Announcements

- Our schedule
 - November 25 (Mon) Tutorial Hour (we are in our lab)
 - November 27 (Wed) Numerical Algorithm (1)
 - November 28 (Thu) Numerical Algorithm (2)
 - December 2 (Mon) Numerical Algorithm (3)
- Questionnaire: December 2, last 10 minutes, bring your laptop!
- 2nd Report: Deadline is **November 28, 9:00am.**
- Final Exam: **December 4 (Wed) 10:50-12:30**
