# Introduction to Algorithms and Data Structures 

12. Advanced Algorithms: Dynamic Programming

Professor Ryuhei Uehara, School of Information Science, JAIST, Japan.
uehara@jaist.ac.jp
http://www.jaist.ac.jp/~uehara
http://www.jaist.ac.jp/~uehara/course/2020/myanmar/

## Developing Algorithms based on Dynamic Programming

Objects: optimization problems
problem of finding an optimal solution among those satisfying given constraints.

## Problem solving by dynamic programming

1. Characterize a structure of an optimal solution.
2. Define an optimal solution recursively. (construct a solution using solutions to subproblems)
3. Compute a value of an optimal solution in a bottom-up manner (in the way to fill in a table)
4. Construct an optimal solution using information obtained. (not only finding a value of an optimal solution but also constructing an optimal solution by following in the table)

## Term of "Dynamic Programming"

- Dynamic programming has no concrete definition (as far as I know); it is a method/strategy/idea that

1. Define a problem recursively, and
2. Solve the problem without (exponential) recursions

- We show "examples" that dynamic programming technique works

1. Combinations (like Fibonacci)
2. Longest common subsequence
3. Knapsack problem (NP-complete problem!?)
4. Chained matrix product

## Number of combinations

Problem P1: Compute the number $\mathrm{C}(\mathrm{n}, \mathrm{k})$ of combinations to choose k items from n different items.

Using the formula,

$$
\begin{aligned}
& \mathrm{C}(\mathrm{n}, \mathrm{k})=\mathrm{C}(\mathrm{n}-1, \mathrm{k}-1)+\mathrm{C}(\mathrm{n}-1, \mathrm{k}), \text { if } 0<\mathrm{k}<\mathrm{n}, \\
& \mathrm{C}(\mathrm{n}, 0)=\mathrm{C}(\mathrm{n}, \mathrm{n})=1 .
\end{aligned}
$$

Therefore, we have the following program.

```
int C(int n, int k){
    if(k==0 | k==n) return 1;
    return C(n-1,k-1)+C(n-1,k);
}
```

Analysis of computation time:
Let $\mathrm{T}(\mathrm{n}, \mathrm{k})$ be time to compute $\mathrm{C}(\mathrm{n}, \mathrm{k})$. Then, we have $\mathrm{T}(\mathrm{n}, \mathrm{k})=\mathrm{T}(\mathrm{n}-1, \mathrm{k}-1)+\mathrm{T}(\mathrm{n}-1, \mathrm{k})$. Thus, $\mathrm{T}(\mathrm{n}, \mathrm{k})=\mathrm{O}(\mathrm{C}(\mathrm{n}, \mathrm{k}))$.
This is an exponential function.

Let's analyze behavior of the program!

How is the function called
The function is called many times for the same value.
Example: $\mathrm{C}(3,2)$ is called twice. $\rightarrow$ redundant
If we store the value $C(n, k)$ as the $(\mathrm{n}, \mathrm{k})$ element of an array when it is first computed, then the same value is never computed twice. Basically, it suffices to fill in the table.

Fill in the table $\mathrm{C}(\mathrm{n}, \mathrm{k})$ !
Formula: $\mathrm{C}(\mathrm{n}, \mathrm{k})=\mathrm{C}(\mathrm{n}-1, \mathrm{k}-1)+\mathrm{C}(\mathrm{n}-1, \mathrm{k})$ If the values in the $(\mathrm{n}-1)$-st row are available, $\mathrm{C}(\mathrm{n}, \mathrm{k})$ is easily computed. $\rightarrow$ Thus, we should fill in the table from the 1st row.

|  | 0 | 1 | 2 | 3 | 4 | 5 |  | 0 | 1 | 2 | 3 | 4 | 5 |  | 0 | 1 | 2 | 3 | 4 | 5 |  | 0 | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 |  |  |  |  |  | 0 | 1 |  |  |  |  |  | 0 | 1 |  |  |  |  |  | 0 | 1 |  |  |  |  |  |
| 1 | 1 | 1 |  |  |  |  | 1 | 1 | 1 |  |  |  |  | 1 | 1 | 1 |  |  |  |  | 1 | 1 | 1 |  |  |  |  |
| 2 | 1 | 2 | 1 |  |  |  | 2 | 1 | 2 | 1 |  |  |  | 2 | 1 | 2 | 1 |  |  |  | 2 | 1 | 2 | 1 |  |  |  |
| 3 |  |  |  |  |  |  | 3 | 1 | 3 | 3 | 1 |  |  | 3 | 1 | 3 | 3 | 1 |  |  | 3 | 1 | 3 | 3 | 1 |  |  |
| 4 |  |  |  |  |  |  | 4 |  |  |  |  |  |  | 4 | 1 | 4 | 6 | 4 | 1 |  | 4 | 1 | 4 | 6 | 4 | 1 |  |
| 5 |  |  |  |  |  |  | 5 |  |  |  |  |  |  | 5 |  |  |  |  |  |  | 5 | 1 | 5 | 10 | 10 | 5 | 1 |

Each element of the table can be computed in constant time.
Thus, the total time is
$\mathrm{O}\left(\mathrm{n}^{2}\right)$.

C program is as follows:
int C(int n, int k) \{
$\mathrm{C}[0][0]=1$;
for $(\mathrm{i}=1 ; \mathrm{i}<=\mathrm{n} ; \mathrm{i}++)\{$
$\mathrm{C}[\mathrm{i}][0]=1 ; \mathrm{C}[[\mathrm{i}][\mathrm{i}]=1$; for $(\mathrm{j}=1 ; \mathrm{j}<\mathrm{i} ; \mathrm{j}++$ )
$\mathrm{C}[\mathrm{i}][\mathrm{j}]=\mathrm{C}[\mathrm{i}-1][\mathrm{j}-1]+\mathrm{C}[\mathrm{i}-1][\mathrm{j}] ;$
\}
return $\mathrm{C}[\mathrm{n}][\mathrm{k}]$;
\}

## Naive Algorithm 2 :

Exercise E1: Investigate an algorithm that computes C $(\mathrm{n}, \mathrm{k})$ based on the Naïve idea in linear time such that it computes $C(n, k)$ correctly if $C(n, k)$ itself does not overflow.

Using the formula $C(n, k)=\frac{n!}{(n-k)!k!}$, it can be computed in $O(n)$.
Here, note that this algorithm may suffer from numerical overflow.

## Longest Common Subsequence

Problem P3: Given two strings A and B of lengths $n$ and m, find the longest substring common to both of them.

Example: For $\mathrm{A}=\mathrm{G}$ A A T T C A G T T A and $\mathrm{B}=\mathrm{G}$ G A T C G A, the longest common substring is GATCA.

```
A= GAATTC AGTTA
B=GGA T CGA
```

Any substring $\mathrm{A}^{\prime}$ of A is a substring of B if characters of $\mathrm{A}^{\prime}$ appear in the same order in the string $B$.
$\rightarrow$ It can be determined in linear time.

> Exercise E3: Write a program to determine whether the first string of two input strings is a substring of the second string in linear time.

## Algorithm P3-A0: (Brute-Force Algorithm) <br> For each substring $\mathrm{A}^{\prime}$ of a string A , determine whether $\mathrm{A}^{\prime}$ is a substring of a string B, and finally output the longest common substring.

Analysis of computation time:

- There are $2^{\mathrm{n}}$ different substrings of a string of length n .
- If this substring is longer than the string B, obviously it is not a substring of $B$.
- Otherwise, each test takes $O(m)$ time.
- Thus, the total time is $\mathrm{O}\left(2^{\mathrm{n}} \mathrm{m}\right)$ time.

Is it possible to have faster algorithm?
Is there any polynomial-time algorithm?

## Algorithm P3-A1:

$$
A=a_{1} a_{2} \ldots a_{n}, B=b_{1} b_{2} \ldots b_{m}
$$

$L[i, j]=$ the length of the longest substring common to $a_{1} a_{2} \ldots a_{i}$ and $\mathrm{b}_{1} \mathrm{~b}_{2} \ldots \mathrm{~b}_{\mathrm{j}}$

## Observation:

(0) if $\mathrm{i}=0$ or $\mathrm{j}=0, \mathrm{~L}[\mathrm{i}, \mathrm{j}]=0$.
(1) $a_{i}=b_{j} \rightarrow L[i, j]=L[i-1, j-1]+1$
(2) $\mathrm{a}_{\mathrm{i}} \neq \mathrm{b}_{\mathrm{j}} \rightarrow \mathrm{L}[\mathrm{i}, \mathrm{j}]=\max \{\mathrm{L}[\mathrm{i}, \mathrm{j}-1], \mathrm{L}[\mathrm{i}-1, \mathrm{j}]\}$

```
A=GAATTC AGTTA
B= GGATC GA
    when a}\mp@subsup{\textrm{a}}{\textrm{i}}{}=\mp@subsup{\textrm{b}}{\textrm{j}}{
```

$\mathrm{A}=\mathrm{GAATTC}$ AGTTA
$\mathrm{B}=\mathrm{GGATCG} \mathrm{A}$
when $\mathrm{a}_{\mathrm{i}} \neq \mathrm{b}_{\mathrm{j}}$

Therefore, it suffices to fill in the table $\mathrm{L}[\mathrm{i}, \mathrm{j}]$ in order. Since the table size is $\mathrm{n} \times \mathrm{m}$, it takes $\mathrm{O}(\mathrm{nm})$ time.

```
Algorithm P3-A1:
for \((\mathrm{i}=0 ; \mathrm{i}<=\mathrm{n} ; \mathrm{i}++\) )
    \(\mathrm{L}[\mathrm{i}][0]=0\);
\(\operatorname{for}(\mathrm{j}=0 ; \mathrm{j}<=\mathrm{m} ; \mathrm{j}++)\)
    \(\mathrm{L}[0][\mathrm{j}]=0\);
for \((\mathrm{i}=1 ; \mathrm{i}<=\mathrm{n} ; \mathrm{i}++\) )
    for \((\mathrm{j}=1 ; \mathrm{j}<=\mathrm{m} ; \mathrm{j}++\) )
        if \((\mathrm{a}[\mathrm{i}]==\mathrm{b}[\mathrm{j}]) \mathrm{L}[\mathrm{i}][\mathrm{j}]=\mathrm{L}[\mathrm{i}-1][\mathrm{j}-1]+1\);
    else \(\mathrm{L}[\mathrm{i}][\mathrm{j}]=\max \{\mathrm{L}[\mathrm{i}][\mathrm{j}-1], \mathrm{L}[\mathrm{i}-1][\mathrm{j}]\}\);
return \(\mathrm{L}[\mathrm{n}][\mathrm{m}]\);
```

Example for the case A=XYXXZXYZXY and B=ZXZYYZXXYXXZ
$A=X \quad Y \quad X X Z X Y Z X Y$, $B=Z X Z Y Y Z X X Y X X Z$

|  | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |

| 7 | 0 | 1 | 2 | 2 | 3 | 3 | 3 | 4 | 4 | 5 | 5 | 5 | 5 |
| 8 | 0 | 1 | 2 | 3 | 3 | 3 | 4 | 4 | 4 | 5 | 5 | 5 | 6 |
| 9 | 0 | 1 | 2 | 3 | 3 | 3 | 4 | 4 | 5 | 5 | 6 | 6 | 6 |
| 10 | 0 | 1 | 2 | 3 | 4 | 4 | 4 | 5 | 5 | 6 | 6 | 6 | 6 |

## Construction of an optimal solution

The value of an optimal solution is obtained by filling in the table. How can we construct an optimal solution achieving the value?

In the problem of finding the longest common substring, we want to find not only the length (value of an optimal solution) but also the longest such substring (optimal solution) itself.

When we fill in the table, we memorize which table element determined L[i][j].

```
(1) \(a_{i}=b_{j} \rightarrow L[i, j]=L[i-1, j-1]+1\)
    (i-1, \(\mathrm{j}-1\) ) is memorized
(2) \(\mathrm{a}_{\mathrm{i}} \neq \mathrm{b}_{\mathrm{j}} \rightarrow \mathrm{L}[\mathrm{i}, \mathrm{j}]=\max \{\mathrm{L}[\mathrm{i}, \mathrm{j}-1], \mathrm{L}[\mathrm{i}-1, \mathrm{j}]\}\)
    if \(\mathrm{L}[i, j-1]>\mathrm{L}[\mathrm{i}-1, \mathrm{j}]\) then \((\mathrm{i}, \mathrm{j}-1)\) is memorized, and
    otherwise, \((\mathrm{i}-1, \mathrm{j})\) is memorized.
```

## Concrete program

```
for(i=1;i<n; i++)
    for(j=1; j<m; j++){
        if(A[i]== B[j]){
            L[i][j] = L[i-1][j-1] + 1;
            B1[i][j] = i-1; B2[i][j] = j-1;
        } else {
            L[i][j] = max2(L[i][j-1], L[i-1][j]);
            if(L[i][j-1]> L[i-1][j]){
                L[i][j] = L[i][j-1];
                B1[i][j] = B1[i][j-1]; B2[i][j] = B2[i][j-1];
            } else {
                L[i][j] = L[i-1][j];
                B1[i][j] = B1[i-1][j]; B2[i][j] = B2[i-1][j];
            }
    }
}
Exercise E4: Write a program in practice to see its behavior.
```

For the case: $\mathrm{A}=\mathrm{XYXXZXYZXY} \mathrm{~B}=$,
Table for backtrack

|  | 2 | 3 |  |  |  |  |  |  | 10 | 11 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $1(0,0)$ |  |  |  |  |  |  |  |  | (0,9 |  | (0,10) |
| $2(0,0)$ |  |  |  |  |  |  |  |  |  |  |  |
| $(0,0)$ | ( | 0,1 | 1,3) | (1, | $(1,4)$ |  | (2, | (1,8) | $(2,9)$ |  |  |
| $4(0,0)$ | $(3,1)$ | (0,1 | 1,3) | (1, | $(1,4)$ | (3, | (3,7) | $(3,7)$ | (3, |  |  |
| (4,0) | $(3,1)$ | (,2 | (1,3) | (1, | $(4,5)$ | (3, | (3, | $(3,7$ | $(3,9)$ |  |  |
| $6(4,0)$ | (1) | $(4,2)$ |  |  | $(4,5)$ |  | (5 |  |  |  |  |
| $7(4,0)$ | ,1 | (,2) | 6, | (6, | $(4,5)$ | (5, | (5 |  |  |  |  |
| 8 (7,0) | ( 1 | (7,2) | 6,3 | $(6,4)$ | ) | (5, | (5,7) |  |  |  |  |
| $9(7,0)$ | $(8,1)$ | $(7,2)$ | 6,3) | $(6,4)$ | $(7,5)$ | $(8,6)$ | (8, | $(6,8)$ | $(8,9)$ |  |  |
| 0 (7,0) | (8,1) |  |  |  |  |  | $(8,7)$ |  |  |  |  |

If we trace the table from $\mathrm{L}[10][12]$ in reverse order, $\mathrm{L}[10][12] \rightarrow \mathrm{L}[7][11] \rightarrow \mathrm{L}[5][10] \rightarrow \mathrm{L}[3][9] \rightarrow \mathrm{L}[2][7] \rightarrow \mathrm{L}[1][4] \rightarrow \mathrm{L}[0][1]$ $\mathrm{a}[8] \mathrm{b}[12] \mathrm{a}[6] \mathrm{b}[11] \mathrm{a}[4] \mathrm{b}[10] \mathrm{a}[3] \mathrm{b}[8] \mathrm{a}[2] \mathrm{b}[5] \mathrm{a}[1] \mathrm{b}[2]$
Thus, the longest common substring is
123456789A 123456789ABC
XYXXZXYZXY ZXZYYZXXYXXZ XYXXXZ

## Problem P4: (Knapsack Problem)

Given $n$ objects $\mathrm{o}_{\mathrm{i}}(\mathrm{i}=1, \ldots, \mathrm{n})$ and their weights $\mathrm{w}_{\mathrm{i}}$, prices $\mathrm{v}_{\mathrm{i}}$, and the capacity (or weight limit) C of a knapsack, find an optimal way of packing objects into the knapsack to meet the capacity constraint in such a way that the total price is maximized.

Input: $\mathrm{I}=\left\{\mathrm{w}_{1}, \ldots, \mathrm{w}_{\mathrm{n}} ; \mathrm{v}_{1}, \ldots, \mathrm{v}_{\mathrm{n}} ; C\right\}$. A solution is represented by a subset $S$ of $\{1,2, \ldots, n\}$.
An optimal solution is such a set $S$ satisfying the
Capacity constraint $\quad \sum_{\mathrm{i} \in \mathrm{S}} \mathbf{w}_{\mathrm{i}} \leqq \mathrm{C}$
and maximizing
total sum of prices $\sum_{i \in S} v_{i}$.
Assumption: Assume that weight of any object does not exceed the capacity C because any object with weight exceeding C is never selected.

Example: Consider the case in which $\left(\mathrm{w}_{1}, \ldots, \mathrm{w}_{5}\right)=(2,3,4,5,6)$, $\left(\mathrm{v}_{1}, \ldots, \mathrm{v}_{5}\right)=(4,5,8,9,11), \mathrm{C}=10$.
$\mathrm{V}[\mathrm{k}]=$ value of an optimal solution for objects up to the k -th one.
Then, by the definition

$$
\mathrm{V}[1] \leqq \mathrm{V}[2] \leqq \cdots \leqq \mathrm{V}[\mathrm{n}] .
$$

In this example, we have

$$
\begin{aligned}
& \mathrm{V}[1]=\mathrm{v}_{1}=4, \mathrm{w}_{1}=2 \leqq \mathrm{C}, \\
& \mathrm{~V}[2]=\mathrm{v}_{1}+\mathrm{v}_{2}=4+5=9, \mathrm{w}_{1}+\mathrm{w}_{2}=2+3 \leqq \mathrm{C}, \\
& \mathrm{~V}[3]=\mathrm{v}_{1}+\mathrm{v}_{2}+\mathrm{v}_{3}=4+5+8=17, \mathrm{w}_{1}+\mathrm{w}_{2}+\mathrm{w}_{3}=2+3+4 \leqq \mathrm{C}, \\
& \mathrm{~V}[4]=\mathrm{v}_{1}+\mathrm{v}_{2}+\mathrm{v}_{4}=4+5+9=18, \mathrm{w}_{1}+\mathrm{w}_{2}+\mathrm{w}_{4}=2+3+5 \leqq \mathrm{C}, \\
& \mathrm{~V}[5]=\mathrm{v}_{3}+\mathrm{v}_{5}=8+11=19, \mathrm{w}_{3}+\mathrm{w}_{5}=4+6 \leqq \mathrm{C} .
\end{aligned}
$$

Here, $\{1,2,3,4\}$ is not a solution since the total weight exceeds the capacity 10 .

In this example, an optimal solution to a subproblem may not be included in an optimal solution. Thus, we cannot apply Dynamic Programming to find a solution in the above order.

Then, what about a method to examine all possible ways of choosing objects?

For each object there are two ways, to choose or not to choose.
$\Rightarrow$ there are $2^{\mathrm{n}}$ ways to choose objects.
It takes exponential time if we examine all possible cases.

## To apply Dynamic Programming, an optimal solution must be defined recursively so that it includes a solution to a subproblem.

$\mathrm{D}[\mathrm{i}, \mathrm{j}]=$ the largest total price among all possible ways to choose objects from objects $1, \ldots, i$ so that the total weight is $j$. It is 0 if there is no way to choose them so that the total weight is $j$.

If an optimal solutions for objects $1, \ldots, \mathrm{i}-1$ is known, we just consider two cases, to add an object i and not to add it. Thus, we have $\mathrm{D}[\mathrm{i}, \mathrm{j}]=\max \left\{\mathrm{D}[\mathrm{i}-1, \mathrm{j}], \mathrm{D}\left[\mathrm{i}-1, \mathrm{j}-\mathrm{w}_{\mathrm{i}}\right]+\mathbf{v}_{\mathrm{i}}\right\}$

This implies the property of Optimal Substructure.

Example: Let $\left(\mathrm{w}_{1}, \ldots, \mathrm{w}_{5}\right)=(2,3,4,5,6),\left(\mathrm{v}_{1}, \ldots, \mathrm{v}_{5}\right)=(4,5,8,9,11), \mathrm{C}=10$. $\mathrm{i}=1 \rightarrow$ only two ways to choose object 1 or not choose it:

$$
\mathrm{D}\left[1, \mathrm{w}_{1}\right]=\mathrm{D}[1,2]=\mathrm{v}_{1}=4, \mathrm{D}[1, \mathrm{j}]=0, \mathrm{j} \neq 2
$$

$\mathrm{i}=2 \rightarrow$ there are four cases: $\},\{1\},\{2\},\{1,2\}$

$$
\mathrm{D}[2,2]=4, \mathrm{D}[2,3]=5, \mathrm{D}[2,5]=9, \mathrm{D}[2, \mathrm{j}]=0 \mathrm{j} \neq 2,3,5
$$

| k | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 1 | 4 |  |  |  |  |  |  |  |  |
| 2 | 4 | 5 |  | 9 |  |  |  |  |  |
| 3 | 4 | 5 | 8 | 9 | 12 | 13 |  | 17 |  |
| 4 | 4 | 5 | 8 | 9 | 12 | 13 | 14 | 17 | 18 |
| 5 | 4 | 5 | 8 | 9 | 12 | 13 | 15 | 17 | 19 |

indicates a new solution

$$
\begin{aligned}
& \mathrm{w}_{1}=2, \mathrm{v}_{1}=4 \\
& \mathrm{w}_{2}=3, \mathrm{v}_{2}=5 \\
& \mathrm{w}_{3}=4, \mathrm{v}_{3}=8 \\
& \mathrm{w}_{4}=5, \mathrm{v}_{4}=9 \\
& \mathrm{w}_{5}=6, \mathrm{v}_{5}=11
\end{aligned}
$$

We can ignore a set of objects if their total weight exceeds 10.1840

```
Algorithm P4-A0:
Input:n objects of(i=1,\ldots,n): weight wind and price }\mp@subsup{v}{i}{}\mathrm{ , capacity C.
for(i=1; i<=C; i++)
    D[0,i] = 0;
for(k=1; k<=n; k++)
    for(i=1; i<=C; i++)
    if(i<ww})D[k,i]= D[k-1,i]
    else {
        if(D[k-1,i-\mp@subsup{w}{i}{}]+\mp@subsup{v}{i}{}}>>D[k-1,i]
        D[k,i] = D [k-1,i-w w ] + vi;
        else
        D[k,i] = D[k-1, i];
        }
max=0;
for(i=1; i<=C; i++)
    if(D[n,i]>max) max = D[n,i];
return max;
```

We maintain not only the table $\mathrm{D}[\mathrm{i}, \mathrm{j}]$ but also the combination to give the value of $\mathrm{D}[\mathrm{i}, \mathrm{j}]$.
$\mathrm{D}[\mathrm{i}, \mathrm{j}]=\max \left\{\mathrm{D}[\mathrm{i}, \mathrm{j}-1], \mathrm{D}\left[\mathrm{i}-\mathrm{w}_{\mathrm{j}} \mathrm{j} \mathbf{j}-1\right]+\mathrm{v}_{\mathrm{j}}\right\}$
$\mathrm{T}[\mathrm{i}, \mathrm{j}]=\mathrm{j}$ if $\mathrm{D}[\mathrm{i}, \mathrm{j}]=\mathrm{D}\left[\mathrm{i}-\mathrm{w}_{\mathrm{j}}, \mathrm{j}-1\right]+\mathrm{v}_{\mathrm{j}}$
$\mathrm{T}[\mathrm{i}, \mathrm{j}]=0$ if $\mathrm{D}[\mathrm{i}, \mathrm{j}]=\mathrm{D}[\mathrm{i}, \mathrm{j}-1]$
Then, we can construct an optimal solution by tracing back the value of D from $\mathrm{D}[\mathrm{i}, \mathrm{n}]$ giving the optimal solution.

| k | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |

Values of $\mathrm{D}[\mathrm{i}, \mathrm{j}] / \mathrm{T}[\mathrm{i}, \mathrm{j}]$
The value of an optimal solution is given by $\mathrm{D}[5,10]=19$.
$\mathrm{D}[5,10]=19, \mathrm{~T}[5,10]=5 \neq 0$, output object 5 .
Since $\mathrm{w}_{5}=6$, its predecessor is $\mathrm{D}[4,10-6]=\mathrm{D}[4,4]$,
$\mathrm{D}[4,4]=8, \mathrm{~T}[4,4]=0$, output nothing. The predecessor is $\mathrm{D}[3,4]=8$.
$\mathrm{D}[3,4]=8, \mathrm{~T}[3,4]=3 \neq 0$, output object 3 .
Since $\mathrm{w}_{3}=4$, its predecessor is $\mathrm{D}[2,4-4]=\mathrm{D}[2,0]$.
Now the total weight becomes 0 , and thus this is the end.
After all, the set of objects for an optimal solution is $\{3,5\}$.

```
Algorithm P4-A1:
Input:n objects of(i=1, .., n): weight }\mp@subsup{\textrm{w}}{\textrm{i}}{}\mathrm{ and price }\mp@subsup{\textrm{v}}{\textrm{i}}{}\mathrm{ , capacity C.
for(i=0; i<=C; i++)
    D[0,i] = T[0,i]=0;
for(k=1;k<=n;k++)
    for(i=1; i<=C; i++)
    if(i< whk ){ D[k,i] = D[k-1,i];T[k,i]=0;}
    else {
        if(D[k-1,i-w w}]+\mp@subsup{v}{k}{}>D[k-1,i]
            {D[k,i]= D[k-1,i-\mp@subsup{w}{k}{}]+\mp@subsup{v}{k}{};T[k,i]=k;}
        else
            {D[k,i]= D[k-1, i];T[k,i]=0;}
        }
k=0;
for(i=1;i<=C; i++)
    if(D[n,i]>D[n,k])k=i;
for(i=n; i>0 && k>0; i--)
    if(T[i,k]>0) {
    Output T[i,k]; k = k - wi
    }

\section*{Analysis of Running Time}

From the structure of the algorithm the computation time is given by \(\mathrm{O}(\mathrm{nC})\).
(1) If the capacity C is polynomial in the number n of objects \(\Rightarrow\) this computation time is a polynomial in \(n\).
(2) If C is much larger than n .

The value C itself can be represented by \(\log \mathrm{C}\) bits.
\(\Rightarrow\) Time is proportional to an exponential function in input size.
It is called a pseudo-polynomial time algorithm.

> Exercise E5: Algorithm P4-A1 uses two 2-dimensional arrays. Show that one of them can be replaced by a one-dimensional array.

\section*{Problem P5: (Chained Matrix Product)}

Given a sequence of \(n\) matrices \(<\mathrm{A}_{1}, \mathrm{~A}_{2}, \ldots, \mathrm{~A}_{\mathrm{n}}>\), find an order of matrix products to minimize the number of operations to compute the matrix product \(\mathrm{A}_{1} \times \mathrm{A}_{2} \times \ldots \times \mathrm{A}_{\mathrm{n}}\).

Product of a \(\mathrm{p} \times \mathrm{q}\) matrix and \(\mathrm{q} \times \mathrm{r}\) matrix is a \(\mathrm{p} \times \mathrm{r}\) matrix using \(\mathrm{p} \times \mathrm{q} \times \mathrm{r}\) operations (multiplication and addition).

\(3 \times 4\)

\(4 \times 3\)

\(3 \times 3\)

Example : \(\mathrm{A}_{1}=10 \times 20\) matrix, \(\mathrm{A}_{2}=20 \times 5\) matrix, \(\mathrm{A}_{3}=5 \times 25\) matrix. \(\left(\left(\mathrm{A}_{1} \times \mathrm{A}_{2}\right) \times \mathrm{A}_{3}\right)\) require \((10 \times 20 \times 5)+(10 \times 5 \times 25)=2250\) ops.
\(\left(\mathrm{A}_{1} \times\left(\mathrm{A}_{2} \times \mathrm{A}_{3}\right)\right)\) requires \((10 \times 20 \times 25)+(20 \times 5 \times 25)=7500\) ops.
Thus, the former needs less operations.

For product of four matrices, there are many orders for their product.
\[
\begin{aligned}
& \left(\left(\mathrm{A}_{1} \times\left(\mathrm{A}_{2} \times \mathrm{A}_{3}\right)\right) \times \mathrm{A}_{4}\right) \\
& \left(\left(\left(\mathrm{A}_{1} \times \mathrm{A}_{2}\right) \times \mathrm{A}_{3}\right) \times \mathrm{A}_{4}\right) \\
& \left(\left(\mathrm{A}_{1} \times \mathrm{A}_{2}\right) \times\left(\mathrm{A}_{3} \times \mathrm{A}_{4}\right)\right) \\
& \left(\mathrm{A}_{1} \times\left(\left(\mathrm{A}_{2} \times \mathrm{A}_{3}\right) \times \mathrm{A}_{4}\right)\right) \\
& \left(\mathrm{A}_{1} \times\left(\mathrm{A}_{2} \times\left(\mathrm{A}_{3} \times \mathrm{A}_{4}\right)\right)\right)
\end{aligned}
\]

It suffices to obtain the number of operations for aHl of them.
Exercise E6: Prove that there are \(\mathrm{O}\left(4^{\mathrm{n}} / \mathrm{n}^{3 / 2}\right)\) ways for parenthesizations. This is known as the Catalan number.
Hint: Suppose there are \(\mathrm{P}(\mathrm{n})\) ways for parenthesization. In each sequence we can parenthesize it by dividing it between its \(k\)-th and \((k+1)\)-st position into subsequences independently. Thus, we have
\[
P(1)=1
\]
\[
\mathrm{P}(\mathrm{n})=\sum_{\mathrm{k}=1}{ }^{\mathrm{n}-1} \mathrm{P}(\mathrm{k}) \mathrm{P}(\mathrm{n}-\mathrm{k})
\]

Due to Richard P. Stanley, the Catalan number has 207 representations! (See http://www-math.mit.edu/~rstan/ec/)

\section*{Characterize structure of an optimal solution and define the value of an optimal solution recursively.}

To compute the product of 4 matrixes
\(\left(\left(\mathrm{A}_{1} \times\left(\mathrm{A}_{2} \times \mathrm{A}_{3}\right)\right) \times \mathrm{A}_{4}\right) \quad\) last is the product of \(\left(\mathrm{A}_{1}, \mathrm{~A}_{2}, \mathrm{~A}_{3}\right)\) and \(\mathrm{A}_{4}\) \(\left(\left(\left(\mathrm{A}_{1} \times \mathrm{A}_{2}\right) \times \mathrm{A}_{3}\right) \times \mathrm{A}_{4}\right) \quad\) last is the product of \(\left(\mathrm{A}_{1}, \mathrm{~A}_{2}, \mathrm{~A}_{3}\right)\) and \(\mathrm{A}_{4}\) \(\left(\left(\mathrm{A}_{1} \times \mathrm{A}_{2}\right) \times\left(\mathrm{A}_{3} \times \mathrm{A}_{4}\right)\right)\) last is the product of \(\left(\mathrm{A}_{1}, \mathrm{~A}_{2}\right)\) and \(\left(\mathrm{A}_{3}, \mathrm{~A}_{4}\right)\)
\(\left(\mathrm{A}_{1} \times\left(\left(\mathrm{A}_{2} \times \mathrm{A}_{3}\right) \times \mathrm{A}_{4}\right)\right)\) last is the product of \(\mathrm{A}_{1}\) and \(\left(\mathrm{A}_{2}, \mathrm{~A}_{3}, \mathrm{~A}_{4}\right)\)
\(\left(\mathrm{A}_{1} \times\left(\mathrm{A}_{2} \times\left(\mathrm{A}_{3} \times \mathrm{A}_{4}\right)\right)\right) \quad\) last is the product of \(\mathrm{A}_{1}\) and \(\left(\mathrm{A}_{2}, \mathrm{~A}_{3}, \mathrm{~A}_{4}\right)\) If we know an optimal orders for subsequences, it suffices to check the three ways of partitions.
\[
\left(\left(\mathrm{A}_{1}, \mathrm{~A}_{2}, \mathrm{~A}_{3}\right), \mathrm{A}_{4}\right),\left(\left(\mathrm{A}_{1}, \mathrm{~A}_{2}\right),\left(\mathrm{A}_{3}, \mathrm{~A}_{4}\right)\right),\left(\mathrm{A}_{1},\left(\mathrm{~A}_{2}, \mathrm{~A}_{3}, \mathrm{~A}_{4}\right)\right)
\]

Generally, the problem is the place for the first partition.
\[
\left(\left(\mathrm{A}_{1}, \ldots, \mathrm{~A}_{\mathrm{k}}\right),\left(\mathrm{A}_{\mathrm{k}+1}, \ldots, \mathrm{~A}_{\mathrm{n}}\right)\right) \mathrm{k}=1,2, \ldots, \mathrm{n}-1
\]

If we know an optimal order for computation for each subsequence, then an optimal order for computation is obtained.

Let the size of each matrix be \(p_{i} \times q_{i}\). Then, only if we have
\[
\mathrm{q}_{1}=\mathrm{p}_{2}, \mathrm{q}_{2}=\mathrm{p}_{3}, \ldots, \mathrm{q}_{\mathrm{n}}=\mathrm{p}_{\mathrm{n}+1}
\]
the product of those matrices is defined.
Thus, we only specify \(\mathrm{p}_{1}, \mathrm{p}_{2}, \ldots, \mathrm{p}_{\mathrm{n}}, \mathrm{p}_{\mathrm{n}+1}\) for input.
If we take the product of matrices from \(\mathrm{A}_{\mathrm{i}}\) to \(\mathrm{A}_{\mathrm{j}}\) then the \(p_{i} \times q_{j}=p_{j+1}\) matrix is obtained.

We define as follows:
\(\mathrm{M}[i, j]=\) the smallest number of computations to calculate the product of matrices from \(A_{i}\) to \(A_{j}\).

We define as follows:
\(M[i, j]=\) the smallest number of computations to calculate the product of matrices from \(\mathrm{A}_{\mathrm{i}}\) to \(\mathrm{A}_{\mathrm{j}}\).

For the computation it suffices to evaluate all possible productions of matrices from \(A_{i}\) to \(A_{k}\) and those from \(A_{k+1}\) to \(A_{j}\) for each \(k\) between i and j .

The product for \(A_{i}\) through \(A_{k}\) is a \(p_{i} \times p_{k+1}\) matrix, and that for \(A_{k+1}\) through \(A_{j}\) is a \(p_{k+1} \times p_{j+1}\) matrix.

Thus, the number of operations to compute them is \(p_{i} p_{k+1} p_{j+1}\).
Therefore, the recurrence equation for \(\mathrm{M}[\mathrm{i}, \mathrm{j}]\) is
\[
\mathrm{M}[\mathrm{i}, \mathrm{j}]=\min \left\{\mathrm{M}[\mathrm{i}, \mathrm{k}]+\mathrm{M}[\mathrm{k}+1, \mathrm{j}]+\mathrm{p}_{\mathrm{i}} \mathrm{p}_{\mathrm{k}+1} \mathrm{p}_{\mathrm{j}+1}, \mathrm{k}=\mathrm{i}, \mathrm{i}+1, \ldots, \mathrm{j}-1\right\} .
\]
```

algorithm P5-A0:
input: matrix sizes ( $\mathrm{p}_{1}$ rows $\mathrm{p}_{2}$ columns), $\left(\mathrm{p}_{2}, \mathrm{p}_{3}\right), \ldots,\left(\mathrm{p}_{\mathrm{n}}, \mathrm{p}_{\mathrm{n}+1}\right)$.
for $(\mathrm{i}=1 ; \mathrm{i}<=\mathrm{n} ; \mathrm{i}++$ )
$\mathrm{M}[\mathrm{i}, \mathrm{i}]=0$;
$\operatorname{for}(\mathrm{d}=1 ; \mathrm{d}<=\mathrm{n} ; \mathrm{d}++)$
for $(\mathrm{i}=1 ; \mathrm{i}<=\mathrm{n}-\mathrm{d} ; \mathrm{i}++)$
$\mathrm{j}=\mathrm{i}+\mathrm{d}$;
$\operatorname{msf}=\mathrm{M}[\mathrm{i}, \mathrm{i}]+\mathrm{M}[\mathrm{i}+1, j]+\mathrm{p}_{\mathrm{i}} \mathrm{p}_{\mathrm{i}+1} \mathrm{p}_{\mathrm{j}+1} ;$
for $(k=i ; k<j ; k++)$
$\operatorname{if}\left(\mathrm{M}[\mathrm{i}, \mathrm{k}]+\mathrm{M}[\mathrm{k}+1, \mathrm{j}]+\mathrm{p}_{\mathrm{i}} \mathrm{p}_{\mathrm{k}+1} \mathrm{p}_{\mathrm{j}+1}<\mathrm{msf}\right)$
$m s f=M[i, k]+M[k+1, j]+p_{i} \mathrm{p}_{\mathrm{k}+1} \mathrm{p}_{\mathrm{j}+1} ;$
$\mathrm{M}[\mathrm{i}, \mathrm{j}]=\mathrm{msf} ;$
\}
return $\mathrm{M}[1, \mathrm{n}]$;

```

Exercise E7: The above algorithm only finds the value of an optimal solution. Modify it so that an optimal order of computation is also obtained.
